

2. What is the process to create a new FHIR resource using Postman and HAPI FHIR server?

To create a new resource open the Swagger UI to review the documentation for the resource type and confirm that a POST request is used. Then, open Postman and create a new request. Set the HTTP method to POST, enter the resource endpoint URL, and paste a valid JSON example of the resource into the Body section using raw JSON format.

3. What is the process to manage authentication when using Postman with a HAPI FHIR server?

Authentication in Postman is managed through the authorization tab for the request. The user selects the authentication type required by the FHIR server and then provides the needed credentials or token before sending the request. The REST API documentation is used to determine what authentication method the server expects.

4. How can you handle error responses from the HAPI FHIR server when using Postman?

Error responses can be handled by checking both the HTTP status code and the response body returned by the HAPI-FHIR server in Postman. The response body may contain details explaining what went wrong, such as an invalid endpoint, incorrect resource type, malformed JSON, or authentication problems.
